

# Models of Creative Destruction (Quality Ladders)

Prof. Lutz Hendricks

October 27, 2021

# Motivation

We study models of process innovation (“quality ladders”).

New issues:

1. Innovations replace existing monopolies - creative destruction.
2. Multiple firms can produce the same good - price competition.

# Baseline Model

# A Baseline Model

- ▶ Demographics: There is a single, infinitely lived household.
- ▶ Preferences:

$$\int_0^{\infty} e^{-\rho t} u(C_t) dt \quad (1)$$

- ▶ Endowments:
  - ▶ 1 unit of work time each instant
  - ▶ households also own all firms / patents

# Commodities

At date  $t$  we have:

- ▶ 1 final good  $Y$ . Used for consumption, R&D, and production of intermediates.
- ▶ A unit measure of intermediate inputs, indexed by  $v$ .

Each intermediate good can be produced with many different “qualities.”

- ▶  $q(v, t)$  is the best quality available at  $t$ .
- ▶ But previously invented qualities are not forgotten.

Innovation takes the form of introducing better qualities.

## Final Goods Technology

There is one final good that can be used for consumption, investment in R&D, and production of intermediate inputs:

$$Y_t = C_t + X_t + Z_t \quad (2)$$

Final goods are produced from labor and intermediates:

$$Y_t = (1 - \beta)^{-1} L_t^\beta \int_0^1 q(v, t) x(v, t)^{1-\beta} dv \quad (3)$$

There is a unit measure of intermediates.

$q(v, t)$  is the best available quality of intermediate  $v$  at  $t$ .

Assumption: Only the best quality is used in equilibrium.

► Details

## Technology: Innovation

- ▶ Each innovation takes the quality from  $q(v, t)$  to  $\lambda q(v, t)$ .
- ▶ The quality step is  $\lambda > 1$ .
- ▶ Innovation takes place separately for each  $v$ .
- ▶ Investing  $Z(v, t)$  for interval  $\Delta t$  creates 1 quality improvement with probability:

$$n(v, t)\Delta t = \frac{\eta}{q(v, t)}Z(v, t)\Delta t \quad (4)$$

- ▶ Over a short interval:

$$q(v, t + \Delta t) = \begin{cases} q(v, t) & \text{with probability } 1 - n(v, t)\Delta t \\ \lambda q(v, t) & \text{with probability } n(v, t)\Delta t \end{cases} \quad (5)$$

## Technology: Intermediate Goods

- ▶ Intermediates perish in production.
- ▶ Their marginal cost is  $\psi q(v, t)$ .

$$\int_0^1 x(v, t) q(v, t) \psi = X_t \quad (6)$$

- ▶ Note:  $q(v, t)$  shows up in various places in such a way to ensure balanced growth.

# Market Arrangements

- ▶ Final goods: perfect competition.
- ▶ Innovators received permanent patents for the qualities they create.
  - ▶ Other firms can improve on their qualities.
- ▶ Intermediate goods firms are the same as innovators (or innovators sell qualities at competitive prices).
  - ▶ They are monopolists
  - ▶ but there is a competitive fringe of firms offering lower qualities
- ▶ Assumption: Current monopolists cannot innovate.
  - ▶ not binding: they would not want to innovate b/c their gain in profits is lower than the gain for new entrants.
- ▶ Free entry into innovation.
- ▶ Households own the innovating firms and receive their profits.

# Equilibrium

Allocation:  $C_t, X_t, Z_t, Y_t$  and  $q(v, t), x(v, t)$ .

Prices:  $p^x(v, t), V(v, t), r_t, w_t$ .

Such that:

1. Agents “maximize” (below).
  - 1.1 household: choose  $C$
  - 1.2 final goods firm:  $Y, L, x$
  - 1.3 intermediate goods firm:  $p^x, V$
  - 1.4 innovators: free entry,  $Z$
2. Markets clear.

A wrinkle:  $q(v, t)$  is stochastic. So the equilibrium def is slightly wrong.

Assumption: Invoke a law of large numbers to ensure that aggregates are deterministic.

# Market clearing

Goods: Resource constraint

Labor:  $L = 1$

Intermediates: implicit in notation

Assets: details omitted

Solving agents' problems

# Household

- ▶ Again: avoid writing out the budget constraint.
- ▶ Just note that the household owns a portfolio of assets (shares of intermediate goods firms) with deterministic rate of return  $r(t)$ .
- ▶ Euler equation:

$$g(C(t)) = \frac{r(t) - \rho}{\theta} \quad (7)$$

- ▶ Value of assets held:

$$a(t) = \int_0^1 V(v, t) dv \quad (8)$$

- ▶  $V(v, t)$  is the value of the intermediate input firm  $v$ .
- ▶ TVC:  $\lim_{t \rightarrow \infty} e^{-rt} a(t) = 0$  [with constant interest rate].

## Final goods firm

$$\max Y_t - w_t L_t - \int_0^1 p^x(v, t) x(v, t) \quad (9)$$

where

$$Y_t = (1 - \beta)^{-1} L_t^\beta \int_0^1 q(v, t) x(v, t)^{1-\beta} dv \quad (10)$$

FOCs:

$$x(v, t) = \left( \frac{q(v, t)}{p^x(v, t)} \right)^{1/\beta} L \quad (11)$$

$$w_t = \beta Y_t / L_t \quad (12)$$

Solution:  $Y_t, L_t, x(v, t)$  that solve 2 FOCs and production function.

## Intermediate goods firm

Static profit maximization with constant demand elasticity  $1/\beta$ .

But there is always a competitive fringe that offers the previous quality at marginal cost price  $\psi$ .

Two possible outcomes:

1. **Drastic** innovation: the monopoly price is lower than  $\psi$ .  
Owner of current best quality can set monopoly price:

$$p^x(v, t) = \frac{\psi q(v, t)}{1 - \beta} \quad (13)$$

2. **Non-drastic** innovation: set  $p = \psi$ .

Solution:  $p^x(v, t)$ .

# Innovators

Free entry

- ▶ increase innovation  $Z$  until marginal cost = present value of profits

Marginal cost is stochastic

- ▶ quality improvements arrive at random

Profits are stochastic

- ▶ monopolies are destroyed at random by competitor's innovation

## Free entry

Suppose current quality is  $q(v,t)/\lambda$ . (simplifies notation)

Investing  $Z(v,t)$  for period  $\Delta t$  incurs cost  $Z(v,t)\Delta t$ .

Marginal benefit

- ▶ a patent valued at  $V(v,t|q(v,t))$
- ▶ with probability

$$n(v,t)\Delta t = \frac{\eta}{q(v,t)/\lambda} Z(v,t)\Delta t \quad (14)$$

## Innovators

If marginal benefit < marginal cost: no innovation (not interesting).

Otherwise: innovation continues until

$$\underbrace{Z(v,t)\Delta t}_{\text{marginal cost}} = \underbrace{V(v,t|q)\frac{\lambda\eta}{q(v,t)}Z(v,t)\Delta t}_{\text{marginal benefit}} \quad (15)$$

Or:

$$\frac{q(v,t)}{\lambda\eta} = V(v,t|q) \quad (16)$$

## Value of innovation

$V(v, t|q)$  is the expected present value of profits

- ▶ tricky to evaluate because of stochastic monopoly duration

**General asset pricing equation** (which we will derive later...):

$$rp = \dot{p} + d \quad (17)$$

In words:

- ▶ the current payoff of the asset consists of capital gain  $\dot{p}$  and dividend  $d$ .
- ▶ rate of return = [current payoff] / [current price]

## Value of innovation

Applying the asset pricing equation to the value of the firm:

- ▶ Current price:  $p = V(v, t, |q)$ .
- ▶ Dividend: Flow profit:  $d = \pi(v, t)$ .
- ▶ Capital gain:  $\dot{V}(v, t|q) - z(v, t|q)V(v, t|q)$ .
- ▶ Lose profit flow at rate  $z(v, t|q)$  - endogenous, chosen by competitors.

Pricing equation:

$$r(t)V(v, t|q) = \pi(v, t|q) + \dot{V}(v, t|q) - z(v, t|q)V(v, t|q) \quad (18)$$

## Digression: Capital Gain

One might expect the capital gain to be

$$(1 - z)\dot{V} - zV \quad (19)$$

Write out payoffs over interval  $\Delta t$

$$rV = \frac{\pi\Delta t + e^{-z\Delta t}\dot{V}\Delta t - (1 - e^{-z\Delta t})V}{\Delta t} \quad (20)$$

Take  $\Delta t \rightarrow 0$  and note

- ▶  $\frac{e^{-z\Delta t}\dot{V}\Delta t}{\Delta t} \rightarrow \dot{V}$
- ▶  $\frac{(1 - e^{-z\Delta t})V}{\Delta t} \rightarrow zV.$

## Equilibrium Characterization

# Equilibrium

For simplicity: assume **balanced growth**.

Start from the Euler equation

$$g(C(t)) = \frac{r(t) - \rho}{\theta} \quad (21)$$

We need to find  $r$ .

## Finding $r$

Use free entry:

$$\frac{q(v,t)}{\lambda\eta} = V(v,t|q) \quad (22)$$

where

$$r(t)V(v,t|q) = \dot{V}(v,t|q) + \pi(v,t|q) - z(v,t|q)V(v,t|q) \quad (23)$$

We need profits.

## Finding profits

$$\pi(v, t) = [p^x(v, t) - \psi q(v, t)]x(v, t) \quad (24)$$

From the intermediate input firm

$$p^x(v, t) = \frac{\psi q(v, t)}{1 - \beta} \quad (25)$$

Normalize  $\psi = 1 - \beta$ , so that  $p^x = q$ .

Then demand is

$$x(v, t) = L \quad (26)$$

Profits:

$$\pi(v, t) = \beta q(v, t)L$$

## Finding $V$

Assume  $\dot{V}(v, t|q) = 0$  (not obvious yet).

- ▶ Intuition: Replacement probability and profits are constant over time.

Pricing equation:

$$rV(v, t|q) = \dot{V}(v, t|q) + \pi(v, t|q) - z(v, t|q)V(v, t|q) \quad (27)$$

$$= 0 + \beta q(v, t)L - z(v, t|q)V(v, t|q) \quad (28)$$

or

$$V(v, t|q) = \frac{\beta q(v, t)L}{r + z(v, t|q)} \quad (29)$$

The probability of losing the business  $z$  acts like a higher interest rate  $r$ .

## Free entry

$$V(v, t|q) = \frac{\beta q(v, t)L}{r + z(v, t|q)} = \frac{q(v, t)}{\lambda \eta} \quad (30)$$

or

$$r + z(v, t|q) = \lambda \eta \beta L \quad (31)$$

This means:  $z(v, t|q) = z^*$  in all sectors with innovation.

## Could there be sectors without innovation?

- ▶ No -  $V$  is present value of expected profits.
- ▶ Without innovation in sector  $v$ :  $z(v, t|q) = 0$ .
- ▶ That raises the value of the firm to

$$V(v, t|q) = \frac{\beta q(v, t)L}{r} > \frac{q(v, t)}{\lambda \eta} \quad (32)$$

- ▶ There would be strictly positive profits for entrants.

## Balanced Growth

We have almost found  $r$ , except that we still need to know  $z^*$ :

$$r = \lambda \eta \beta L - z^* \quad (33)$$

We get  $z^*$  from the balanced growth condition  $g(C) = g(Y)$ .

Intuition:

- ▶ suppose  $r$  is high; then  $g(C)$  is high
- ▶ innovation is not profitable (strong discounting of profits)
- ▶  $g(Y)$  will be slow

## Output Growth

Define average quality:  $Q(t) = \int_0^1 q(v, t) dv$ .

Final output with  $x(v, t) = L$ :

$$Y_t = (1 - \beta)^{-1} L_t^\beta \int_0^1 q(v, t) L^{1-\beta} dv \quad (34)$$

$$= (1 - \beta)^{-1} L Q(t) \quad (35)$$

Output growth:  $g(Y) = g(Q)$ .

## Quality Growth

Consider an interval  $\Delta t$  - small.

Fraction  $z^* \Delta t$  varieties experience 1 innovation.

The rest experiences no innovation.

For small  $\Delta t$  the probability of multiple innovation is negligible.

## Quality Growth

Therefore:

$$Q(t + \Delta t) = \int_0^1 [(z^* \Delta t)\lambda q(v, t) + (1 - z^* \Delta t)q(v, t)] dv \quad (36)$$

$$= (z^* \Delta t)\lambda Q(t) + (1 - z^* \Delta t)Q(t) \quad (37)$$

$$Q(t + \Delta t) - Q(t) = Q(t)(\lambda - 1)z^* \Delta t$$

$$\dot{Q}(t) = Q(t)(\lambda - 1)z^*$$

Growth rate:

$$g(Q(t)) = (\lambda - 1)z^* \quad (38)$$

Intuition:

- ▶  $Q$  is average  $q$ .
- ▶ Fraction  $z^*$  of all  $qs$  (chosen at random) grow at rate  $\lambda - 1$ .
- ▶ Fraction  $1 - z^*$  experience no growth
- ▶ Since growth is not correlated with  $q$ , growth of average = average of  $q$  growth

## Balanced Growth

$$g(Q) = (\lambda - 1)z^* \quad (39)$$

$$= g(C) \quad (40)$$

$$= \frac{\lambda \eta \beta L - z^* - \rho}{\theta} \quad (41)$$

Solve for  $z^*$  and

$$g(C) = \frac{\lambda \eta \beta L - \rho}{\theta + (\lambda - 1)^{-1}} \quad (42)$$

# Properties of Balanced Growth

- ▶ No transitional dynamics.
  - ▶ it turns out only  $Q$  matters, not the entire distribution of  $q(v)$
- ▶ Symmetry: all varieties share the same rate of innovation  $z^*$  - this is what makes the model tractable.
- ▶ The static allocation is not optimal
  - ▶ monopoly pricing distorts  $x(v, t)$

# Optimality

Is the level of innovation too above or below what maximizes “welfare”?

The answer is usually ambiguous.

1. The innovator does not capture the entire consumer surplus.
2. Business stealing effect: innovation destroys competitor profits.
3. Replacement effect: innovation destroys the innovator's own profit.

See Acemoglu 2009, ch. 14.1.

# The Role of Patents

Innovation only occurs, if the innovator earns monopoly status for some time

- ▶ but see Boldrin and Levine (2008)

The trade-off:

- ▶ Stronger patents - higher profits - more innovation.
- ▶ Stronger patents distort prices.

# Applications I

## Sources of growth: Jones (2002)

- ▶ basic idea: U.S. growth in output per worker has been 2% per year for a long time
- ▶ but not a balanced growth path
- ▶ growth has been propped up by rising schooling, R&D investment/output
- ▶ once these level off, growth should decline to 0.4% p.a.

## Trade and growth:

- ▶ Lucas (2009), McGrattan and Prescott (2009), Acemoglu et al. (2013)
- ▶ trade effectively increases market size
- ▶ scale effects imply output gains

## Skill-biased technical change:

## Applications II

- ▶ Acemoglu (2007)
- ▶ when skilled labor is abundant, firms invest to make it more productive
- ▶ explains why skill premium has risen even as supply of skilled labor increased

Optimal patent design:

- ▶ Hall (2007), Jones and Williams (2000), Jones and Williams (1998)

Effects of taxes on growth:

- ▶ Peretto (2007)

# Reading

## Only the best quality is used

Why is only the best quality used?

For each good  $v$ , a large number of qualities are offered (by monopolists):  $q(s, v, t)$ .

They are perfect substitutes in the production of final goods.

Think of the production function as

$$Y_t = (1 - \beta)^{-1} L_t^\beta \int_0^1 X(v, t)^{1-\beta} dv \quad (43)$$

$X(v, t)$  is input of all vintages of good  $v$ :

$$X(v, t) = \left[ \int_{-\infty}^t q(s, v, t)^{1/(1-\beta)} x(s, v, t) ds \right] \quad (44)$$

## Only the best quality is used

When patent owners for all vintages  $s$  compete (see Ch. 12), pricing ensures that only the vintage with the highest  $q$  is used in equilibrium.

$$X(v, t) = q(v, t)^{1/(1-\beta)} x(v, t) \quad (45)$$

where  $q(v, t) = \max_s q(s, v, t)$ .

## Only best quality is used

- ▶ Let's focus on one good and suppress the  $(v, t)$  arguments for notational clarity.
- ▶ In the production function (??) all qualities  $s$  of the same good are perfect substitutes.
- ▶ The Firm minimizes the cost of  $X(v, t) = \int q(s)^{(1/1-\beta)} x(s) ds$ .
- ▶ The cost is  $\int p(s)x(s)ds$ .
- ▶ The firm uses the goods with the highest ratio of "quality" to price:  $q(s)^{1/(1-\beta)}/p(s)$ .
- ▶ The monopolist charges markup  $\psi$ :  $p(s_{Mon}) = \psi q_{Mon}$ .
- ▶ Competitors charge at least marginal cost  $p(s) = q(s)$ .
- ▶ The innovation is drastic if the monopolist has the highest quality/price ratio:

$$\lambda^{1/(1-\beta)}/(\lambda \psi) > 1 \quad (46)$$
